Note from Steve August, B.A., Dip. Physio

Thank you for buying the Backpod. The views and recommendations contained in this user guide are my own. They are those of a New Zealand manual physiotherapist with 30 years' experience. This amounts to over 40,000 patient treatments performed personally, plus innumerable courses, conferences, clinical discussions, reading, etc. Views on the strengths and limitations of other treatment and care approaches are fair comment from the viewpoint of a very experienced practitioner.

Why you have neck or upper back pain - the iHunch

Pain in the neck and upper back is an enormous and rapidly increasing problem. Here's how big: of 740 million people in Europe, conservative statistics show that perhaps 100 million will be in acute pain right now, including headaches. Forty-eight million people in the USA and 70,000 in New Zealand will have a problem right now. You are not alone! What's going on?

Here's how it happens. We all start out upright: watch four-year-olds running around with their heads balanced perfectly above their shoulders. But then we all bend forward to do things – in school and on into adult life. Do enough of this and the upper/middle back tightens into that bent-forward hunch.

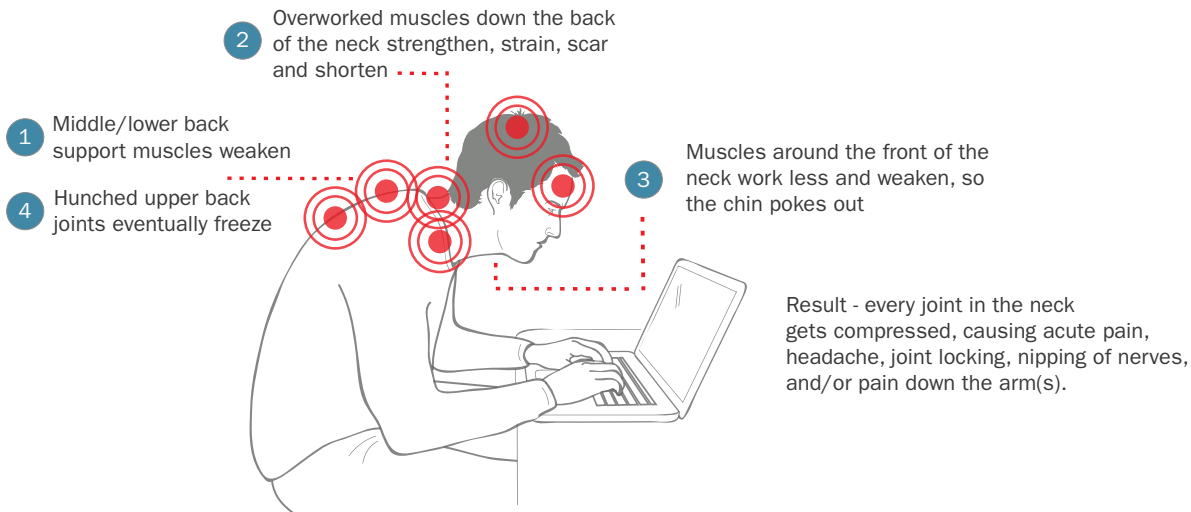

Then the muscles along the back of the neck have to work several times harder just to hold the head up – and they strain, scar and tighten. This puts a compressive load on the joints in the neck giving them a tendency to eventually jam up and lock, which can cause acute pain and headaches. In the worst cases discs and nerves become involved, with pain spreading down the arms. Whiplash and impact injuries also take their toll, but that upper back hunching probably underlies the majority of

upper back and neck problems in the world today. See the iHUNCH page on the Backpod's website www.backpod.co.nz.

And it's getting worse. This forward-bending stoop has accelerated in the last few years with the advent of laptops, tablets, smartphones and similar - see the Wikipedia entry on the iHunch. Unlike desktop computers you can't detach the keyboards from the small screens, so users tend to hunch forward even more. What to do?

The good news is that because it all happens in a logical pattern, you can treat it logically and effectively. But you have to treat all the pieces causing the problem. Often health professionals are so busy or specialised they treat only one or two, so you tend to get only very temporary relief. The Backpod is a high-tech mobilising tool which uses your own upper body weight to let you stretch out the tightened hunched upper and middle back which commonly underlies most neck problems. So you can keep things free - ongoing.

This user guide also provides the basic stretching and strengthening exercises, home massage and postural techniques that you need to treat and care

for your own upper back and neck at home. These aren't time-consuming or complicated. They are also available free as videos on our website www.backpod.co.nz - on the iHunch page.

It's fine if you're already receiving help from a doctor, physiotherapist, osteopath, chiropractor, pharmacist or acupuncturist; doing Pilates or yoga; working out at the gym; etc. The Backpod and its programme will generally help and enhance all these other approaches. They provide stand-alone treatment and maintenance for most middle back

and neck problems, but if your specific problem needs extra help, your health practitioner is there to provide it. We all want you, the patient, to get better, and stay that way.

The second part of this user guide is for doctors, physiotherapists, osteopaths, chiropractors and other health professionals. It contains more detailed information on how the Backpod will help their particular treatment approach. The Backpod and its programme are highly effective complements to each speciality.

Instructions: How to use the Backpod®

View our two instruction videos on YouTube:
'How To Use The Backpod'
(shorter and longer version)

The Backpod is designed to stretch out a bent-forward and stiffened upper and middle back, and rib cage. When the joints in the spine have jammed up enough, and the very tough tissue surrounding them has tightened, you can't free them up using your own muscles or body movements. It's no longer enough to just "sit up straight" – you haven't got the leverage to unlock a specific joint or stretch out the stiffened ligaments around it on your own.

You can do it with the help of the Backpod though. Your own body weight provides the force, and the shape of the Backpod localises it to the particular

areas that need to free up.

The stretch provided by the Backpod can be strong, **so the first time you use it, start off with three pillows under your head**, and if necessary layers of fluffy towel over the Backpod itself. This will make the stretch more comfortable. **It should definitely not be actually painful.** However, the Backpod is a real treatment device, not a gimmick, and you could feel some slight discomfort to start off with. It's like stretching a muscle – if you couldn't feel anything, then you wouldn't be doing anything useful. See the few warnings and precautions on pages 7&8.

1 Place the Backpod on the floor, flat side down. (A bed or mattress gives an even milder start to stretching.) Sit on the floor with your knees bent up and your feet on the floor, and gently lower yourself onto the Backpod so that it lies lengthwise under your spine between your shoulder-blades – as shown in the picture on the front cover of this user guide.

2 Place your hands behind your head, and let your shoulders and back relax. **Hold your chin in slightly.** You may feel some slight discomfort but this will usually disappear inside a minute as the spine stretches out a bit. If you think it's still too sore, just add some more padding over the Backpod.

3 Relax in this position for 30-60 seconds. Let your elbows also relax and drop back towards the floor, which will stretch your chest muscles. Breathe slowly and deeply. Any initial discomfort should ease off.

4 Every 30-60 seconds change your position about 50mm (2 inches). Work the Backpod up and down your middle back and about the same distance out to both sides. Don't go up the spine as high as your neck or lower than the bottom of your rib cage. Most tightness occurs around the shoulder blades, so concentrate on that area. **Also position the Backpod about 50mm (2 inches) out to one side of the spine**

between it and the shoulder blades to mobilise the rib joints, which can get tight just as the spine does. Spend several minutes working around the whole middle and upper back area like this. You can do this once a day at home or at work, most days a week. If the spine feels too tender, stretch only every second day.

5 When stretching with the three pillows becomes comfortable, you can make the stretch stronger by using just **two pillows**. When that feels acceptable drop back to **one**, and then to **no pillow at all**. Depending on how tight your back is, it may take weeks to get to this point. Stick with it – it's very tough material you're loosening, and it may have been frozen up for many years. It usually takes three weeks or so for things to mostly free up, but this can vary.

For a stronger stretch, turn the Backpod sideways across your spine. (The tighter curve across the Backpod will apply more localised pressure to your back.) Or lift your buttocks off the floor. Or slowly keep moving your linked hands over your head and back down to your waist. Chase the tightest spots and stay on them for 1-3 minutes. Or combine all of these. You may need this extra leverage especially for the top of your back and ribs.

When all the joints are moving fine, then all you feel (with no pillows) on the Backpod is a satisfying stretch. To keep everything freed up, just use the Backpod once a week, or if things feel like they're getting tight again.

Using the Backpod in a sitting position: You can also use the Backpod in a chair or car seat. Just slip it down between your upper back and the seat and lean back onto it. This sitting position gives a milder stretch than the lying position. When driving a car or truck you can push back against the steering wheel to give a stronger stretch against the Backpod, so it's an excellent opportunity for plenty of stretching when commuting or on a long trip.

Further treatment: The Backpod can stretch out a tight spine more effectively than anyone can with just their own exercises. But some spines can be so tight that they also need manipulation or mobilisation from a manipulating doctor, physiotherapist, osteopath or chiropractor. These practitioners can unlock joints so that the Backpod can then stretch them the rest of the way, and then keep them free. It's a perfect combination - and avoids ongoing repeated manipulations.

Care of your Backpod®

The Backpod itself consists of a strong rigid polycarbonate core (the transparent blue inner part) with a cushioning synthetic rubber outer layer (the flexible apple-green part). The inner core is sculpted to stretch your spine when you lie back on the Backpod and the cushioning outer layer is there to make this comfortable enough.

The Backpod is immensely strong – polycarbonate is the same material used in jet fighter windshields. We've driven a BMW over one to test it for Europe and a Jeep Cherokee to test it for the USA. The Backpod was fine both times. So we don't think it's going to break when anyone lies on it, and we think it will last for many, many years.

Any dust or fluff on the outer green layer can usually be brushed or wiped off with a dry tea-towel or bath towel. More resistant dust or fluff may need wiping off with a warm, damp sponge or towel.

Any oils, such as massage oil or perspiration, should be wiped off as the residue may reduce the life of the green synthetic rubber outer layer. Use a warm, damp sponge or towel, and also mild soap if necessary.

Do not wash the Backpod under a tap or submerge it in a sink or basin – the internal core may fill up with water.

Do not put the Backpod in the microwave, dishwasher, washing machine or oven.

Do not remove the flexible green outer layer of the Backpod as bending it backwards may possibly cause internal cracks in the synthetic rubber.

Cracks on the inside of the green outer layer are not grounds for return of the Backpod because they can only happen if the green layer is pulled off - don't do this.

Warnings and precautions

When used sensibly, the Backpod is safe to use for almost all common musculoskeletal conditions involving the upper back, middle back and neck.

It is a passive device and entirely under the user's control. The only force applied comes from the user's own upper body weight which they can lower gently to lie on the Backpod. They can get off again if there are problems. Bodystance Ltd is not liable for any damage or injury resulting from non-directed or non-sensible use of the Backpod, its user guide or website videos.

If problems or pain persist when using the Backpod or following its programme, see your doctor or other appropriate health practitioner. It is not possible to build a single product perfectly suited to every patient; however, the Backpod and its programme should benefit the vast majority of upper back and neck problems. That the Backpod and its programme do not fully solve your particular problem is not grounds for the return of the product – we don't know if you have used it correctly, there may be other things going on, and you may need specific health practitioner intervention(s) as well. You do need to decide for yourself if it is appropriate.

Treatment soreness.

Any effective stretch of tight muscles, joints, tendons or ligaments may produce some discomfort, even mild soreness – just like any warm-up muscle stretch. This doesn't do any harm. Patients commonly describe a “good pain, which is doing the right thing.” It can often happen as things that have been tight for a long time start to free up.

Use of the Backpod should be graded with pillows and even layers of fluffy towel over the Backpod itself so it's not too uncomfortable on any one stretch. Stretching only every second day is recommended if the spine is too tender. If pain is clearly extreme, or persists for more than a day or two, see your doctor or other health professional.

Don't use the Backpod if there is reason to suspect a bony fracture, cancer or other relevant medical conditions.

Don't use the Backpod in the presence of recent surgery, wounds, bruising, infections, shingles or other skin lesions in the area. Watch that any catch on a bra strap doesn't dig in painfully.

Don't use the Backpod for children. Their bones are still growing and their joints are usually fully flexible anyway. However, the Backpod's programme of muscle strengthening, posture education and home massage can be extremely helpful. It is also available as videos on our website

www.backpod.co.nz.

Osteoporosis and osteopenia

These are conditions of reduced bone density, making the bones more at risk of a fracture. The Backpod should be used with increased caution, but mild degrees of these conditions are not a total contra-indication. The Backpod provides only a passive stretch of the spine, and can be gently graded by using pillows under the head and padding over the Backpod itself. If unsure, check with your doctor first.

Scheuermann's Osteochondritis

The Backpod may irritate this condition when it is in the inflammatory phase. However, it is highly appropriate for treatment of the common tight flexed middle and upper back that remains once the inflammation has settled. If unsure, check with your doctor first.

Straight or concave middle and upper backs

This is the one fairly common case where the standard use of the Backpod won't help. About 4% of middle backs are straight or even slightly hollowed. This is usually because of a fall on the back or other impact, or an excessively rigid upright posture.

The Backpod used in the usual way will push these spines further in the wrong direction, causing compressive loading on the joints at the back of the bony vertebrae, which can then jam.

If you think you might have this sort of back, just get someone to look at your spine between the shoulder-blades. If it's straight or hollowed, and the Backpod is not helping, see your health professional. There is an effective use of the Backpod for this type of spine outlined on page 17 of the Health Practitioner pages: "Backpod for straight or concave thoracic spines". The Backpod programme will help in any case – especially the massage (see pages 13 & 14: "Massage – two simple techniques").

The straightening programme (1): One simple muscle stretch

Flexibility is good for you. In an ideal world, we'd have time to do an hour's stretching every day. If you haven't got that time, here is the single stretch with the greatest benefit for most neck problems. It is for the upper trapezius muscle which runs from the point of your shoulder across to the spine and up to the base of your skull. When you're wearing a backpack, this is the muscle the straps are resting on, and it's what you use when you shrug. It's usually the first one to tighten up with stress and lots of bent forward work. When you see someone with their shoulders held up around their ears, they need this stretch.

This is a simple side-bending stretch, which can be done sitting or standing. Drop one arm and shoulder down towards the ground and stretch your head sideways away from it, using your other hand to pull your head towards your other shoulder. Keep the dropped shoulder relaxed. You can bend your head forward slightly, and rotate it a little, to pull on different fibres of the muscle. When doing this stretch while sitting, tuck the hand of the dropped arm under your buttock to help keep the shoulder dropped.

If you're doing this at home, hold the stretch for 30 seconds, then do the same for the other side. Do two or three stretches if you have time. In a busy and stressful workplace, even a ten-second stretch from time to time will usually stop the muscle straining and tightening.

View our instruction videos online
at www.backpod.co.nz/ihunch

The straightening programme (2): Two simple strengthening exercises

A full gym strengthening programme will do a more thorough job of building up the strength you need to live your busy life. If you can't fit that in, here are the two strengthening exercises giving you the maximum benefit for the time and effort involved.

The common hunched-forward upper back/poked-chin posture which is the basis of most neck and upper back problems has two main areas of muscle weakness. One is around the middle back and includes the muscles which anchor and stabilise the shoulder-blades and stop the upper back from drooping forward. (These include the middle and lower trapezius fibres and the rhomboid muscles.) The second group that gets really weak are the deep muscles around the front of the neck. When this happens, the chin pokes out and the joints at the back of the neck bones are compressed, which can result in joints jamming and trapping of the nerves which run out between the bony vertebrae.

1 To strengthen between the shoulder-blades, lie on your front, arms by your sides with palms upwards, chin tucked in. Squeeze your shoulder-blades together, lift your chest slightly up off the

ground, and lift your straight arms up so they are just off the ground. Hold that position for **five seconds** and then relax. Do it ten times in a row. This is called a 'set'. Rest for a minute, then do another set. Rest for another minute, then do a third set.

Do this exercise at home every day or every second day. When it becomes easy, move your hands inwards so the knuckles are just above each buttock. When that becomes easy, do it holding a half-kilogram (one pound) weight in each hand. Then when that's easy, use a 1kg (2lb) weight; then finally progress to a 2kg (4lb) weight. You can stop there - you're strong enough! If you don't have hand weights, you can use cans of beans for half-kilogram weights, and one-litre plastic bottles filled with water for the 1kg weights, and 2L bottles for the 2kg weights.

2 To strengthen the front neck muscles, lie on your back on the floor with your knees bent and your feet on the floor. Roll your head slightly to tuck your chin in, hold it carefully in, and lift the back of your head only a centimetre or two (half an inch) off the floor. Hold that position for **ten seconds**, then relax and rest. Repeat the exercise until you have done it ten times.

It's most important that this exercise be done accurately – don't let the chin poke out or the head come too far off the floor. To start with, if you can't hold the position for a full ten seconds, just hold it correctly for as long as you can. Also, if you can't do ten lifts in a row, just do as many as you can correctly. Don't be discouraged if it's hard – it may take weeks before you are strong enough to manage ten full ten-second lifts in a row.

If your front neck muscles are really weak, and with your chin held in you can't lift your head off the floor at all - don't give up. It's just where you're starting from and they'll get stronger - muscles are really good at that. Just do the exercise as described in the first paragraph but don't even try to lift the head

off as well. When you can firmly hold your chin in for ten seconds, ten times in a row, and do three lots of that easily enough – then you'll be strong enough to start lifting the head off as well.

The reason for these two exercises is to get the muscles strong enough to use during the day to hold your neck and upper back in a neutral position which won't strain muscles or joints. This is explained on the next page: 'Posture'.

View our instruction videos online
at www.backpod.co.nz/ihunch

The straightening programme (3): Posture

This is easier than you think. The two exercises in the preceding strengthening section will give you the strength you need to hold your neck in a neutral position so that your joints won't jam, even when you are bending forward. Posture is the practical daily application of that strength. It's often explained in a confusing and complicated way and it doesn't need to be. Here's how simple it is:

1 For the neck, hold your chin in a little. Don't let it poke out.

2 For the upper and middle back, hold your shoulders back and down a little. Don't let them hunch.

If you're not sure exactly how far to go, just do both actions as far and as hard as you can, then relax a little from that position. Initially you'll often forget to hold your neck and shoulders like this, but don't give up – it becomes automatic with enough practice, and easy when the muscles get stronger.

One indicator that you're getting it right is that your ear lobe sits vertically above the point of your shoulder. (You can notice someone getting it badly wrong – seen from side on, the back of their head will sit vertically above the front of their chest.)

Posture is important not just for pain relief. Research shows a hunched posture indicates and may even drive a lack of personal confidence, and also correlates strongly with not being listened to.

Perfect posture gets attention. For an inspiring explanation of this, Google Dr Amy Cuddy's TED talk (with over 50 million views) on posture and body language.

See also the 'Perfect Posture' page on the Backpod's website www.backpod.co.nz.

The straightening programme (4): Massage - two simple techniques

In an ideal world, frequent massage would be part of our lives. Failing that, here are the two massage techniques that are of most use in most neck problems. You need a massage partner. If you haven't got someone on hand, find someone else with a neck problem – which shouldn't be too difficult!

The main muscles that need massage run from the base of the skull down the back of the neck to below the shoulder blades, and also out to the points of the shoulders. (The main ones are called the trapezius, rhomboid and levator scapulae muscles.) When they fatigue and strain, small tears occur which scar up as part of their repair process. A build-up of this scarring (called adhesive fibrosis) shortens the muscles, lifting the shoulders up towards the ears and pulling the head back so the chin pokes out.

The upper trapezius stretch shown in the stretching section on page 9 is a good daily way of keeping that part of these muscles elastic but if they are scarred enough they will also need massage. Massage has much more leverage on tight, tough

muscle scarring than just stretching – like a rolling pin flattening out a chunk of dough into a pancake. Deep tissue massage like this shouldn't be done more than once a week – the tissues need time to recover. You will need some massage wax, massage oil or cooking oil to let your fingers slide easily over the skin.

1 Sitting massage position.

Patient: sit at a desk or table with your forehead on a pillow, rolled towel or something else comfortable.

Clasp your hands behind your neck, then slide them up onto the back of your head, pulling your hair up and out of the way. Tuck your chin in so that the muscles at the back of the neck are gently stretched.

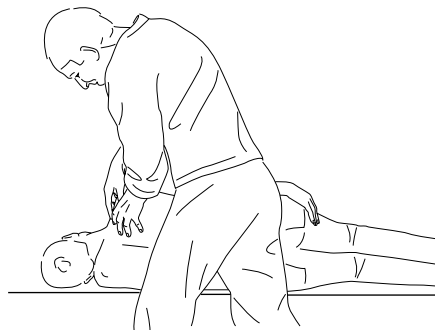

Person massaging: work up and down the neck and back muscles from just below the shoulder blades right up to the base of the skull. Take your time and go gently to start with. Use your fingers, thumbs or knuckles to work the muscle fibres lengthwise. You may feel harder lumpy bits in the muscles – they are the scarred patches so concentrate on them. Spend about 10-15 minutes doing this.

2 Side lying massage position.

Patient: lie on your side, with your head dropped sideways (without a pillow if that's comfortable enough). Your top shoulder should be relaxed and dropped in the direction of your hip, with your hand around your buttock to hold it like that. Your hips and knees should be bent up so you don't roll around. This position stretches the upper trapezius muscle running from the shoulder up the neck to the base of the skull, which is usually the first one to strain and tighten during bent forward work.

Person massaging: massage along the length of this muscle. Concentrate on the hard patch of scar tissue usually found between the shoulder and the neck. Start gently. You can work more deeply into the muscles once they have warmed up. Spend about 5-10 minutes working on each side.

Backpod® combined with manipulation and manual therapy from doctors, physiotherapists, osteopaths and chiropractors

The Backpod is an ideal adjunct to manual or manipulative therapy. Manipulation is excellent for unlocking jammed joints, but they usually won't stay free unless the surrounding tightened capsules and ligaments are also stretched out. The Backpod is ideal for this, so you get a long-term solution, not just a temporary fix.

High velocity short amplitude thrust manipulation is a quick and effective way of banging free a locked spinal apophyseal (facet) or costovertebral (CV, posterior rib) joint. Obviously the usual precautions and contraindications taught to trained manipulators need to be observed.

However, if the joint has been jammed for some time, the surrounding collagenous capsule and ligaments will have tightened around the immobile hinge. Manipulation can free the hinge movement, but the surrounding tight collagen close around it tends to freeze it up again. Collagen is tough and can take up to six months to remodel. This is the main reason for the problem coming back again weeks or only days after an effective manipulation treatment session.

Lying back on the Backpod for several minutes daily

will give a strong sustained stretch to shortened ligaments and capsules around the joints and quietly reduce an excessive thoracic kyphosis. The pressure can be graded for the thoracic facets by positioning the Backpod longitudinally under the spine (a gentler curve) or transversely (a sharper curve, hence more stretch pressure); and by using pillows under the patient's head and even layers of fluffy towel over the Backpod itself. The CV joints are localised by positioning the Backpod longitudinally on the curve of the ribs between the scapula and the spine itself. See pages 3–5: 'Instructions: How to use the Backpod'.

The Backpod works particularly well after manipulation, when the joints have been definitively unlocked so they will move to allow the stretch pressure to directly reach the surrounding collagen. It is also effective before manipulation, to produce some loosening of the hypomobile segments first and make the manipulation easier, both for the therapist and the patient.

The Backpod's programme of posture, massage, strengthening and stretching covers the other aspects of the usual flexed thoracic/chin poked neck problem. For instance, manipulation can effectively and immediately unlock atlanto-occipital (CO/1) joints

jammed in extension and causing headaches – a common problem. But the wider drivers (over-flexed thoracic spine, weak neck flexor muscles, strained scarred upper trapezius muscles, poked chin posture, etc.) that force the C0/1 joints into extension until they freeze also need to be countered, or the problem will rapidly return. The Backpod programme covers each of these necessary components in turn. It is also available as free videos on our website www.backpod.co.nz.

Backpod in conjunction with manual physiotherapy, the McKenzie approach, Mulligan and Maitland techniques, etc.

The Backpod fills a gap in physiotherapy techniques for the common excessively kyphotic thoracic spine. The patient can use it for a stretch lasting several minutes, which is much more effective on chronically shortened collagen than a few seconds of, say, Maitland PAs. It can stretch tightened costovertebral joint capsules in the same sustained way.

Hands-on manual techniques and manipulation can apply greater force to unlock a chronically jammed joint, but a sustained stretch is needed to stop the surrounding tightened collagen just freezing it up again. The Backpod can provide this, with sufficient leverage, and in the patient's own home. A rolled-up towel or tennis ball usually can't.

In my experience the McKenzie treat-your-own-back approach is brilliantly effective for treating bulging

lumbar discs. However, the thoracic spine is reinforced and splinted to a fair extent by the rib cage and chest muscles. So repeated active movements by the patient alone cannot bring as much force to bear on a specific vertebra here as they can in the low back. The Backpod enables the patient to bring the necessary much greater leverage to a section of thoracic spine, and they can do it at home in their own time. The McKenzie approach does include appropriate therapist hands-on mobilisation, of course. The Backpod is a valuable addition to these techniques for the thoracic spine.

Sub-group of straight or concave thoracic spines.

The common manipulation techniques (vertical downward thrust on the thoracic spine or ribs with the patient lying prone, 'knee-in-the-back' or variants, 'dog technique' body drop onto the supine patient with the therapist's fist underneath) are all appropriate for an excessively flexed hypomobile thoracic spine. They jolt the joints in an extension direction to reduce that excessive flexion.

However, there is a small subgroup of patients with thoracic segments locked in extension, indicated clinically by a straight or even concave section of the thoracic spine. These manipulations don't help these segments much, as they tend to shift the joints further into the range they're already locked in. There is a logical and simple solution – see page 17: 'Backpod for straight or concave thoracic spines'.

Backpod® for straight or concave thoracic spines

The common problem with middle/upper thoracic spines is excessive kyphosis from too much bent-forward activity. This leads on to most neck problems as the cervical spine is cranked into excessive extension and joint loading simply to hold the head up, and the upper trapezius muscles which do most of the work strain, scar and shorten.

However, a minority of patients (perhaps 4%) have straight or even concave sections of the thoracic spine where the segments are locked in extension. This is usually the result of a fall on the back or other impact, or an excessively rigid upright posture. These type of thoracic spines are readily identified simply by looking at the patient from behind.

In my experience, the standard physiotherapy mobilisation technique of oscillating downward pressure on the spinous processes with the patient lying prone (Maitland PAs) will tend to make this sub-group worse, as it increases the extension glide of facets already excessively extended (i.e., it increases the concavity). On the same principle, repeated manipulation similarly tends not to clear the problem.

The Backpod answer to this subgroup is simple and logical. Lay the patient prone with the Backpod

longitudinally under their sternum – you may need to cover it with a folded towel for extra padding. This creates a flexion stretch at the extended thoracic joints. Then glide the spinous processes longitudinally apart using thumbs, fingers and/or hypothenar eminences. This direction of mobilisation glides the facets in a flexion direction, taking them out of their locked end-range extension.

Oscillatory pressure is best initially to get the facets moving, followed by sustained pressure to stretch the shortened capsules and ligaments. It is a technique that can generally be taught to the spouses, partners, friends, etc. of patients for follow-up at home.

Note that these patients with straight or concave thoracic spines can still have tight or frozen costovertebral joints where the ribs hinge onto the backbone. These patients can use the Backpod in the normal way to stretch these posterior rib joints, with the Backpod positioned slightly to either side of the backbone but not over the spine itself. The positioning is over the curve of the ribs, about 40-50mm (2 inches) out from the midline, i.e. between the midline of the spine and the inside edge of the scapula.

Backpod® for scoliosis

The Backpod is a logical and appropriate counter to milder scoliosis in the thoracic spine. Scoliosis is a complex three-dimensional deformity of the spine, ranging from a barely noticeable twist to appallingly severe spinal distortion requiring surgical stabilization. The Backpod can't significantly unwind the extreme cases, but it is a logical and practical approach to opposing the twist in milder examples – fortunately the vast majority.

Milder scoliosis is readily identified in two ways. Seen from behind, as the patient bends forward from standing, one side of their rib cage will show as higher than the other. Similarly, with the patient lying flat on their front with their head not turned to either side (ideally, prone on a plinth with their nose in the nose hole), the posterior curve of the ribs on one side will be raised relative to the other side. This indicates a twist of the thoracic vertebrae towards the raised side.

Keeping it simple and treating it as a pure rotation problem (which it isn't), downward manual pressure on the posterior curve of the raised ribs will use them as levers through the costovertebral joints to 'unwind' the thoracic rotation.

The patient can produce this same pressure at home by lying back on the Backpod with it positioned under the curve of the raised ribs, i.e. about 50mm (2 inches) out from the midline of the spine.

The amount of actual unwinding of the scoliotic twist depends on its severity and chronicity, what is driving it, patient compliance with the Backpod and any exercise programme, etc. However, nearly all scoliotic problems start out mildly, commonly manifesting first in adolescence. As they frequently progress over the years, using the Backpod to oppose, limit and even unwind the torsion where possible is strongly indicated.

Later mild scoliosis often exists in association with an excessive thoracic kyphosis. The Backpod is ideally suited for treating both components of the spinal torsion, being positioned in midline to treat the kyphosis and slightly to the raised side to oppose the scoliosis.

Use of the Backpod should be combined with thorough musculoskeletal assessment, looking for underlying drivers of the scoliosis. These include leg length difference, muscle imbalance, and pelvic torsion associated with sacroiliac joint dysfunction among others. Each identified factor needs to be addressed specifically, for instance using shoe inserts to compensate for a leg length difference, Schroth method or similar gym approach to muscular asymmetries, etc. The common statement that 65% of scoliosis is idiopathic is highly suspect, and probably set so high because in very many cases the underlying drivers have not been understood.

Backpod® for costochondritis, Tietze's Syndrome, 'slipping ribs' and costovertebral (posterior rib) joints

The Backpod's small peaked shape is designed to give a strong, specific stretch to tight posterior rib (costovertebral and costotransverse) joints. Foam rollers and Swiss balls cannot do this. It is positioned longitudinally 40-50mm (about 2 inches) out to the side of the spine, over the curve of the ribs, i.e. between the midline of the spine and the medial (inside) border of the scapula (shoulder blade) - see pages 3 & 4. This ability to stretch tight and frozen posterior rib joints makes the Backpod ideal for treating several conditions:

Costochondritis is a scary and confusing (but not life-threatening) condition with pain where your ribs join onto your breastbone. **Tietze's Syndrome** is just costochondritis with enough inflammation to cause obvious swelling at the rib joints on your breastbone; it's not a whole different entity. The swelling is **not** a systemic or auto-immune inflammation but simply part of the normal inflammatory response to mechanical injury, like the swelling of a sprained ankle, or of a foot blister.

Important - any acute chest pain should always be seen first (and urgently) by a doctor or Emergency Department in case it's your heart. Cheeringly, up to half of presentations of acute chest pain aren't the heart or anything else dire.

Almost all the standard medical statements about costochondritis have almost no evidential basis. It is NOT a mystery, or difficult to fix. Ribs work like bucket handles, hinging at the front onto the sternum (breastbone) at the costosternal joints, and at the back onto the spine (at the costovertebral joints). The ribs lift up and down with each breath, and the rib joints also move with any torso movement.

Now, if the posterior rib joints are tight or immobile, then the more delicate anterior joints where the ribs hinge onto your breastbone HAVE to work excessively, just to let allow breathing. So they strain, get irritated, then get inflamed - and there's the costochondritis. Unlike other strained joints, they can never get a rest, as long as breathing continues. If they get inflamed enough to see obvious swelling then it's called Tietze's Syndrome.

This understanding from New Zealand manual physiotherapy is the only, repeat only, one which explains such specific pain just at the rib joints on the breastbone and nowhere else in the body. All other suggestions and treatments, including the medical ones, miss the point in that they seek to suppress an irritation/inflammation without treating or even recognising the simple mechanical problem driving it.

Anti-inflammatory medications, steroid shots, Vitamin D, omega-3, turmeric, etc. may indeed help the body to better suppress the pain, but do not treat or fix the cause.

Treatment uses the Backpod to free up the tight posterior rib movement. The sustained stretch on the Backpod is able to effectively stretch out the tough shortened collagen surrounding immobile posterior rib joints, enabling a lasting freeing up of the hinge movement. Hands-on treatment (including manipulation) cannot do this, though it may be a necessary addition if the posterior rib joints are very frozen.

Sports massage for the muscles between and overlying the ribs at the back and sides may also be needed; also specific stretching of the intercostal muscles between the ribs. For a detailed explanation and treatment programme, see the COSTOCHONDRITIS page on our website www.backpod.co.nz and also our YouTube video 'How to Fix (most) Costochondritis and Tietze's Syndrome, Part (2): Exercises and Treatment Details.'

'Slipping rib' syndrome has the same cause as costochondritis - the immobile posterior rib movement driving compensatory excessive movement elsewhere,

just to allow breathing and torso movement. In this case, the hypermobility happens to the side of the rib cage at the costochondral junction where the bone of the ribs changes to cartilage. Treatment is essentially the same as for costochondritis, for the same reasons.

Costovertebral (posterior rib) joints can lock acutely in flexion, causing very sharp unilateral local pain slightly to the side of the spine. Passively rotating the seated patient towards the painful side is very much more painful and restricted than rotation away from it; also the pain is reproduced on full inspiration. This is because both these actions require the CV joints to extend, and they have become locked in flexion. Treatment is the same as for costochondritis, though easier because the rib joints on the breastbone have not also become strained.

For other conditions using the Backpod to free up tight rib cage movement, see chronic asthma (page 21) and rib pain in pregnancy (page 22).

View our information, treatment and research videos online at www.backpod.co.nz/costochondritis

Backpod® for chronic asthma, bronchitis and some other respiratory conditions; also rib pain in pregnancy

The Backpod can be surprisingly useful in a number of respiratory conditions, especially chronic asthma and bronchitis. Regardless of the state of the lungs, they cannot fully inflate unless the ribcage can expand fully to allow this. This in turn requires full range of movement at the costovertebral joints where the ribs hinge onto the spine.

This movement has often become quite restricted in patients with **chronic asthma or bronchitis**, especially where the onset has been in childhood, with the patient developing while bent forward trying to suck in enough air. These patients usually exhibit the common excessively hunched thoracic spine, with rounded shoulders sitting more towards the front of the chest. This posture will have become 'set' by the tightening of the collagen of ligaments, capsules, etc. around the restricted rib and spinal joints.

Chronically tightened collagen is extremely tough and responds best to long sustained stretching. The Backpod provides this, with enough leverage to be effective. It is used in the usual way, positioned for about a minute at a time – up and down the middle and upper back to stretch the thoracic hunch, and about 50mm (2 inches) out to the sides of the spine on the curve of the ribs to loosen the rib hinges. The strengthening exercise on page 10: 'Two simple

strengthening exercises' (for the middle back muscles) will probably be needed also to build up the support strength for the area.

As a bonus, the Backpod use position is also ideal for practising deep diaphragmatic (also called 'abdominal') breathing at the same time. While lying on the Backpod, the patient inhales slowly through the nose to a count of ten, then slowly and completely exhales to a similar count. One hand may be placed just below the rib cage to feel the stomach rise as the air is drawn in to the deepest parts of the lungs.

A suitable timing would be three of these slow deep breaths, then move the Backpod 50mm (2 inches) to another position under the spine or ribs. As well as filling the lungs fully, diaphragmatic breathing is also held to reduce anxiety and stress and boost energy and stamina.

A variety of **other lung conditions** can leave behind them a secondary effect of restricted CV joint movement even after the condition has resolved. For instance, the pain of pleurisy can mean that the patient avoids expanding the ribcage fully, and over time the limited rib hinge range becomes 'set' by shortened collagen around the joints. The same process can happen with pneumonia, pulmonary

and radiation fibrosis, other restrictive lung diseases, and neurological conditions such as Guillain-Barré syndrome. The Backpod is ideal for treating the rib cage restriction – an aspect often overlooked by doctors concentrating perfectly correctly on the underlying lung problem.

Rib pain in pregnancy is quite common partway through term as the baby bulge grows bigger. The rib cage needs to expand to accommodate it, and pain results if the joints and muscles are too tight to allow it. The pain can be sharp and severe, and certainly detracts from the experience of bearing a child.

It does not always clear as the pregnancy continues, even though Relaxin hormone release will be facilitating joint hypermobility throughout the body. The suggested mechanism is that Relaxin will soften ligaments but not adhesive fibrosis, so any old scarring restrictions will actually become tighter relative to the other joints as the pregnancy continues - this further explains the onset of pain partway through term. The problem may be becoming much more common, as so many young mothers now start into pregnancy carrying a hunched thoracic spine and rib cage tightness from much use of laptops, tablets and smartphones. (See the Wikipedia entry on the iHunch.)

It doesn't respond well to general stretching, as the already well-moving parts of the rib cage machinery simply stretch more, and the tight bits stay tight.

The restriction is usually at the posterior rib articulations (costovertebral joints) where the ribs join onto the spine, but can include tight, scarred intercostal muscles between the ribs. As well, immobile rib joint movement at the back can cause compensatory overuse straining at the other ends of the rib where they join onto the sternum (breastbone). This is then diagnosed as costochondritis, or Tietze's Syndrome if there is sufficient observable swelling at the rib joints on the sternum as well.

The problem usually responds very well and quickly to the Backpod used slightly to the sides of the spine to stretch free tight posterior rib joints, as for costochondritis and other costovertebral joint problems (see page 19). Tightness and scarring in the intercostal muscles between the ribs responds well to specific stretching of those muscles, by a partner or therapist. The technique is described about ten minutes into the YouTube video 'How to Fix (most) Costochondritis and Tietze's Syndrome, Part (2): Exercises and Treatment Details.' All these conditions affect the middle back.

Backpod® for ankylosing spondylitis, Scheuermann's Osteochondritis, DISH (Forestier's disease) and Parkinson's Disease

Ankylosing spondylitis is a rheumatoid condition that can cause extreme thoracic flexion and eventual fusion of the vertebrae – a severe progression of the hunched-forward/poked-chin pattern of most neck problems. It affects 0.1–0.2% of the population, mostly males. Initially the thoracic spine is painful and inflamed; only in later decades does it become fixed, flexed and fused.

The Backpod and its programme should be used once the condition is diagnosed to slow and possibly even halt the progression into flexion. The Backpod in particular is ideally designed to gently oppose the ongoing flexion contraction. As well, the Backpod used for sacroiliac joint stretches (see pages 25 & 26) will oppose the ongoing tightening at these joints which is part of ankylosing spondylitis.

Scheuermann's Osteochondritis (also known as Scheuermann's disease) is an inflammation affecting the thoracic spine, usually in adolescents. The acute inflammation generally burns itself out after a few years, commonly leaving adhesive fibrosis and locked thoracic segments in its wake. These should respond to the Backpod and its programme in the usual way. However, even the acute inflammatory stage is worth treating cautiously in the same fashion, as why the

spine gets inflamed has not been explained. Excessive flexion stress on the slouching adolescent spine is a reasonable bet, and the Backpod and programme will address that.

Diffuse Idiopathic Skeletal Hyperostosis (DISH or Forestier's disease) is a thoracic spinal tightening that can be treated the same as **ankylosing spondylitis**.

Parkinson's disease is a degenerative disorder of the central nervous system, with motor symptoms resulting from the death of dopamine-generating cells in the mid-brain. The Backpod and its programme cannot help the degenerative progression of the disease, of course. However, they can help with the musculoskeletal consequences, namely the characteristic thoracic hunching, muscular rigidity, neck pain and headache.

The Backpod is ideal to oppose the increasing thoracic kyphosis. This will of itself drive neck pain and headache as the posterior neck muscles strain to simply hold the head up, with Parkinsonian muscular rigidity compounding the problem. The two massage techniques shown on pages 13 & 14 are simple and easy for home carers to use, and a considerable help in alleviating the musculoskeletal pain and headache, on a daily or less frequent basis.

Backpod® for persisting pain after neck or thoracic surgery

Cervical laminectomy or foraminotomy operations are performed to trim back any bony impingement on the nerves as they exit between the vertebrae, usually at the C5/6 or C6/7 level. These patients are typically older, with hunched thoracic spines. Excessive thoracic kyphosis hunching requires the patient to extend their neck just to look ahead, which has a closing down effect on the nerve exit canals, exacerbating any impingement. The Backpod used in the usual way reduces an excessive thoracic kyphosis, thereby reducing the closing down of the cervical nerve exit foramina, and allowing full benefit from the operation.

Further, these hunched patients hold their heads up by overusing the upper trapezius and other neck extensor muscles. These muscles become fatigued, strained and scarred – from adhesive fibrotic repair of the repeated micro-trauma of overuse. The fibrotic scarring and shortening pulls the cervical spine into excessive extension – which closes down the nerve exit canals. This is increased by surgical scarring after a posterior entry operation. These shortened cervical extensors are usually found in conjunction with very weak longus colli and deep neck flexors, giving rise to a poked-chin posture. The Backpod user guide stretches, massage, posture and strengthening exercises will specifically

counter this pattern, so the patient then gets the full and lasting benefits of the operation performed.

Persisting pain after thoracic surgery is an appallingly common problem. This is unsurprising as the stretch on the intercostal (IC) muscles and costovertebral (CV) and sternocostal (SC) joint capsules required for most procedures is massive. Normal adhesive fibrotic repair after such surgery frequently leaves frozen CV joints, plus wound and strain scarring of the IC and other muscles, plus or minus tethering of the IC nerve(s). Ongoing pain is particularly distressing for the patient as every time it hurts they think the original problem is coming back.

Generally, they respond readily to the Backpod used to free up the contracted CV capsules (as outlined on pages 19 & 20); massage in side lying for IC, lat. dorsi, middle and lower trapezius tethering; specific gentle hands-on IC muscle stretching; and therapeutic ultrasound (1.4W/ cm² continuous) for IC nerve tethering at the operation site. Low dose tricyclics such as amitriptyline help with the wound-up nervous pathways in a chronic problem. Usually it is not a full-blown pain syndrome, though often diagnosed as such, especially if T4 syndrome autonomic symptoms are present (see page 27).

Backpod® for sacroiliac joint mobilisations, and coccydynia (tailbone pain)

The Backpod can also be used to mobilise a hypomobile sacroiliac (SI) joint problem such as can commonly occur after a fall onto the low back or coccyx. The impact can often leave the sacrum ‘ridden up’ along the SI joints and jammed in flexion (i.e., nutated). This leaves the tailbone more exposed to impact/pressure when sitting down and creates a chronic coccydynia from the repeated banging on the tip of the coccyx. This type of tailbone pain doesn’t respond to purely local treatment of the tailbone but clears when the SI movement is restored to normal. The extremely tough mix of capsule, ligaments and fascia around hypomobile SI joints means that good results from mobilisation and manipulation techniques are often quite temporary, before the surrounding shortened collagen tightens them up again.

The Backpod is ideal for a sustained stretch of this very tough surrounding collagen and a shearing mobilisation of the joint surfaces. The most basic manual physiotherapy mobilisation technique for the SI joints is a Maitland PA, a vertical oscillation of the sacrum by the therapist while the patient lies prone. The Backpod essentially produces a sustained version of this, using the patient’s own lower body weight to provide the force. The patient lies on their back on the floor, thighs vertical, shins horizontal,

ankles crossed and heel supported on the edge of a table or chair. The Backpod is positioned under the sacrum longitudinally and the patient relaxes onto it for at least several minutes, once or twice daily. It can still take weeks before the SI joint movement is free enough to stay free.

The Backpod leverage on hypomobile SI joints can be enough to free them up on its own, but frequently they are tight enough to need the greater force of a manipulation or specific therapist mobilisation techniques. The Backpod is then the ideal follow-up, to stretch things further and retain the benefits of the treatments.

Clinical Caution: The Backpod should be used to mobilise only restricted *hypomobile* sacroiliac joints. Stretching already excessively moving *hypermobile* SI joint problems will make them worse. The best way to clinically distinguish between the two is Andry Vleeming’s test for SI hypermobility. Briefly, the patient lies on their back and actively lifts one straight leg as high as they can. This is then repeated with the therapist manually pushing both sides of the patient’s pelvis together (i.e., artificially compressing and stabilising the SI joints). If the leg raise is then clearly higher and without pain, it indicates an unstable, hypermobile sacroiliac joint. This should not be

manipulated or mobilised, with the Backpod or any other technique. These problems are best treated by support muscle strengthening and stabilisation belts.

Sacroiliac pain during and after pregnancy is common. Usually it is explained as arising from excessively moving (i.e. hypermobile) and strained SI joints, due to the loosening and softening effect on the ligaments of hormones released during pregnancy to allow the sacrum to hinge open fully to let the baby come through the pelvic basin. This surely happens, however it doesn't explain unilateral SI pain, since all the ligaments are presumably loosening equally. Unpublished New Zealand research and extensive clinical experience suggests that unilateral SI pain appearing partway through pregnancy is more usually from a hypomobile SI. These patients generally have a history of a fall or impact on the low back, pelvis or tailbone, presumably leaving the legacy of an adhered and hypomobile SI joint. The interpretation is that as the pregnancy continues, and the surrounding ligaments get looser, the adhered SI joint becomes relatively more hypomobile and then painful.

These problems generally respond well and quickly to mobilising the hypomobile sacrum with manual physiotherapy techniques, or on the Backpod as shown. This rather validates the model, as the patient is no longer sore - even though the pregnancy is

continuing and the baby is getting bigger - so the pain can't just be coming from the "stresses and strains of pregnancy." If SI or tailbone pain persists months after the baby is born it is then usually coming from SI hypomobility after the ligaments have tightened up again after the birth. The Backpod is equally effective in this situation to gently mobilise the tight SI hinges.

Backpod® for T4 Syndrome and Thoracic Outlet Syndrome

T4 syndrome is essentially an add-on to the common musculoskeletal problems that involve the mid-thoracic vertebrae and ribs. It takes its special character from the proximity of the sympathetic neural chain which travels down the necks of the ribs. This can produce distal sympathetic symptoms including whole hand and/or forearm paraesthesia, swelling, blotchiness and feelings of hot or cold in the hands.

The postulated mechanism is that sustained or extreme thoracic postures can lead to relative ischemia within multiple tissues, triggering the sympathetic signs and symptoms. These may not be derived solely from the fourth thoracic vertebra, hence 'T4 syndrome' may also be referred to as 'upper thoracic syndrome'.

In practical terms, treatment is the same as for the vast majority of local thoracic and/or costovertebral problems, so the Backpod is ideal here. It can be used by the patient to stretch out the common excessive thoracic hunch and/or any hypomobile CV joints, or by the therapist to mobilise the small sub-group of straight or concave thoracic spines as detailed on page 17. The Backpod programme of support strengthening, home massage and posture understanding also applies. Once the thoracic spine and ribs have been restored to full range supported movement, the distal sympathetic symptoms will clear.

Health practitioner additions may include manipulation to unlock any specifically jammed facet or CV hinges, work station adjustment to limit excessive hunching, brachial plexus stretching exercises, and non-steroidal anti-inflammatory medications which are very helpful in the acute phase. Deep sports massage is very useful to tease out built-up adhesive fibrotic scarring fibres in the surrounding muscles, especially around the T4 area and including the rhomboids and middle trapezius, but also the pecs, the lats and the shoulder girdle, and down the affected arm(s).

Thoracic Outlet Syndrome is essentially compression of the nerves and/or blood vessels running through the upper back / clavicle / first rib area. This can cause paraesthesia, pain, numbness and/or claudication down the arm(s), neck and/or upper back. Certainly the entrapment can be structural, e.g. a cervical rib or impinging tight ligaments, often requiring surgical excision or release in a very small minority of cases.

However the wider view is that the common iHunch (see pages 1 & 2) tends to bunch and constrict the muscle and joint movement in this area anyway. So use of the Backpod and its full home program are strongly indicated, especially if specific intervention surgery hasn't worked well. Massage and stretching for pectoralis and scalene muscle scarring and shortening are also indicated, plus nerve stretches and mobilisations.

Backpod® for prescribing doctors, pharmacists, and acupuncturists

The Backpod and its programme are intended to be the most practical and effective home treatment and ongoing care package that can be handed out or recommended to almost all patients with upper back and neck problems. Non-steroidal anti-inflammatory (NSAID) and analgesic medications are excellent at reducing the pain and effect of inflamed and strained joints and muscles. However, they are aimed solely at the inflammation and pain, and can have side-effects such as damage to the lining of the gut.

It is simply good clinical sense to also treat the mechanical pattern of structural tightness and weakness which underlies and drives these acute inflamed episodes – especially as, contrary to a popular view, a large proportion do not just settle down after an acute flare-up. The videos on our website www.backpod.co.nz which teach ongoing home care of the upper spine are free for any patient to access.

Regarding **Costochondritis** and **Tietze's Syndrome**, there is an overview of the existing research in our YouTube video 'Costochondritis and Tietze's Syndrome: The published medical research on how to fix them.'

The common medical understanding of costochondritis as a “mysterious inflammation” is NOT supported by the available research. Our New Zealand manual physiotherapy view is.

Acupuncture: The same comments apply to acupuncture. Flooding the area with endorphins is most useful in the acute phase, but is not likely to rapidly change chronic underlying structural problems. Consider a broken leg: you can acupuncture it but you still have a mechanical problem – the fractured bone. The Backpod and its programme are a practical home package designed to sort out the common pattern of tightness and weakness driving the large majority of upper back and neck pain. This mechanical approach to the underlying drivers of the problem combines extremely well with acupuncture which can contribute to pain relief and healing, especially in the acute phase.

Detailed information and videos on the Backpod's use with a variety of musculoskeletal conditions is available online at www.backpod.co.nz.

Backpod® combined with massage therapy

Most neck problems arise from the common hunched forward/poked chin posture. What holds the chin up in this pattern are the upper trapezius and neck extensor muscles. These overwork, fatigue, and strain, and subsequently adhesive fibrotic scarring is laid down as part of the repair process. Massage is the most effective way of stretching out these tight fibrotic fibres. It can apply more force to a specific area than can a general stretch of the whole muscle.

The techniques shown in pages 13 & 14: 'Massage – two simple techniques' are the most relevant ones for the majority of neck problems. A more comprehensive general massage will obviously do a more thorough job. The usual way of doing massage has the patient lying prone with the head flat, preferably on a massage plinth with a nose hole. I find a more effective way to loosen scarred and shortened fibres in the upper trapezius and posterior neck muscles is to put them on stretch first, so that all the slack is taken up, and then massage them longitudinally. This position is shown on page 13.

The other very common area of muscle overwork, straining and scarring is the upper trapezius muscle between the neck and the shoulder. These fibres overstrain and scar because they come to provide

the major portion of support to the shoulder girdle so the arms and hands can operate, while the middle and lower trapezius fibres become stretched out and weaker. This imbalance tends to get worse unless corrected. One side-lying position to massage these upper trapezius fibres is shown on page 14.

These two massage positions cover the release areas most commonly needed. Good comprehensive massage will pick up other areas of tightness. There are other muscle groups likely to be tight and scarred from repeated work in a hunched position. They include the pectoral muscles as these are in a shortened position when using the hands at, say, a computer keyboard; muscles round the side of the neck, especially sternocleidomastoid; and serratus anterior, which pulls the scapulae forward around the rib cage.

Massage is an essential part of any treatment programme. On its own it will loosen off tight, scarred muscles. However, it will not unlock jammed spinal joints if these are tight enough, and it also won't provide support strength. The other components in the Backpod programme (muscle strengthening, stretching, mobilising, posture and the Backpod itself) will almost certainly also be needed.

Backpod® combined with yoga, the Feldenkrais Method, the Alexander Technique, and ergonomics

Yoga: Reasonable flexibility is good, and yoga is good at producing muscle flexibility. However, if the specific joints in the thoracic spine are too thoroughly jammed, self-stretching does not have the leverage to free them. We can only move our spines by ourselves as a unit, so the parts that are moving well will reduce the force we can bring onto any parts that aren't moving.

The Backpod can bring much more leverage to bear on a specific vertebra, and is a highly effective addition to a yoga session. The same principle applies to scarring inside a muscle. You can stretch the whole muscle with yoga, but often specific massage with its higher leverage is necessary to break down the patch of scarring in it.

The Feldenkrais Method and the Alexander Technique both aim to teach correct, perfectly balanced movement. This is a worthy goal, but again if the spinal joints are sufficiently locked before you start, in my experience they won't free themselves just by moving correctly. The Backpod and its programme provide the specific higher leverage loosening needed to obtain the full benefit from both of these approaches.

Ergonomics: There is a whole area of ergonomics concerned with the appropriate positioning of computer screens and their keyboards for their operators. The advent of laptops, tablets, smartphones and similar devices has made ideal positioning virtually impossible, as their screens cannot be detached from their keyboards. Granted, extra screens or keyboards can be attached, but almost no-one ever does, because of the loss of convenience and portability.

So even more hunching forward is required to use the new devices, hence the surge in neck and upper back problems. Given that people aren't going to stop using the technology, the Backpod and its programme are logical ways to unwind its effects on the spine, ongoing.

For a more detailed analysis of the musculoskeletal consequences of hunching, see the iHUNCH page on the Backpod's website www.backpod.co.nz See also the Wikipedia entry on the iHunch.

Backpod® for gymnasiums, Pilates and personal trainers

The Backpod user guide contains two simple muscle strengthening exercises. These are highly useful, but cannot be as effective as a comprehensive supervised strengthening programme. The usual hunched forward/poked chin neck pattern arising from bent-forward activity leads to a standard imbalance in the muscles involved. The hands are being used, so the pectoral muscles of the chest become strong and tight. However, the retractors of the scapulae (especially the **middle and lower trapezius fibres and rhomboids**) become stretched out and weak.

An indicator of this is a wide gap between the inner edge of the shoulder blades and the spine. This shows the scapulae have migrated around the rib cage, pulled by the tighter, stronger anterior chest muscles. These are not restrained by the weaker stretched-out middle back muscles, giving rise to a stooped-forward upper back and hunched-forward shoulders. So these are the ones that need concentrating on in a strengthening programme to correct a neck or upper back problem.

There are many techniques, but obvious ones to include are the one-arm bent-over dumbbell row (a bit like the action of pull-starting a motor lawnmower), the seated row, lateral pulldown, and the two-arm bent-over barbell row. A high bench, where the client can lie

face-down and pull a barbell up to the underside of the bench, is particularly accurate for this whole group of muscles. Correct form on all these exercises includes the chin held in and the shoulder blades squeezed hard together. The lateral pulldown bar should always come down in front of the face and never behind the head. For gym warm-ups and cardiovascular workouts, use rowing machines and cross-trainers as these work the middle back muscles unlike, say, exercycles.

The other muscles essential to counter the chin-poked-forward posture are the **longus colli and other deep neck flexors**. These hold the chin in, and are usually missed by personal trainers and gym programmes. However, the neck cannot maintain correct posture, with the chin easily held in, unless these muscles are strong enough to do it. They can be surprisingly weak and should always be tested. Frequently, a client with immense strength in the upper trapezius and neck extensors can hardly lift their head off the ground with the chin held in (which requires strength in the deep neck flexors). This is at least partly why they have a neck problem. See page 11 for the strengthening exercise.

About us

The Backpod® is a product from Bodystance Ltd, a New Zealand company bringing practical innovations and solutions to very-large-number musculoskeletal problems worldwide. The Backpod® and its programme were developed and tested in New Zealand, and are immediately applicable to most neck and upper back problems anywhere in the developed world - they are the same spines with the same forces acting upon them.

Bodystance Ltd is registered with Medsafe, the New Zealand Medicines and Medical Devices Safety Authority (www.medsafe.govt.nz) and the Backpod® has been notified to the Medsafe data base for medical devices.

USA: The Backpod® has been approved by the FDA as a classification 1, FDA-exempt medical device.

detailed user
instructions

Find us on:
facebook[®]
/TheBackpod

- 1** To start - Lie back on the floor with your knees bent and your head resting on three pillows.
- 2** Position the Backpod lengthwise under your spine between your shoulder-blades. Add layers of towel over the Backpod for more comfort if desired.
- 3** Place your hands under your head and relax onto the Backpod for 30 seconds. Repeat this stretch several times, re-positioning the Backpod up and down the middle back and slightly out to the sides of the spine.

View our instruction videos on YouTube: 'How To Use The Backpod'

This Bodystance[®] product and its user guide are designed to help the vast majority of upper back, middle back, and neck problems. Your particular problem may also need health practitioner expertise.

See this user guide or our website www.bodystance.co.nz for detailed information and precautions about using the Backpod[®]. If you are unsure, or should pain persist, check with your health professional.
